dilute phase is probably the most common form of pneumatic conveying for this group of materials. A much higher conveying line inlet air velocity must be maintained for di-lute phase systems, even if the material is capable of being conveyed in dense phase. Conveying line inlet air velocities are typically of the order of 2000 to 2400

pneumatic conveying system. If a positive displacement blower is used in combi-nation with a long distance, small bore pipeline, for the suspension flow of a mate-rial, for example, it is quite possible that the entire pressure drop would be utilized in blowing the air through the pipeline and that no material would be conveyed.
